DIABETES

LINKED TO DEFICIENCIES IN KEY MINERALS

People with diabetes often exhibit deficiencies in essential minerals such as magnesium, zinc, chromium, selenium, and iron—all of which play critical roles in blood sugar regulation, insulin sensitivity, antioxidant defense, and energy metabolism.

Low levels of these minerals may impair glucose uptake, increase oxidative stress, and worsen insulin resistance, making proper mineral balance vital for managing and potentially preventing diabetic complications.

CARDIOVASCULAR AND KIDNEY PROBLEMS

Imbalanced calcium-to-magnesium and vitamin D-to-K ratios can cause calcium to build up in arteries and kidneys rather than bones, compromising heart and kidney health. Balancing these nutrients is crucial for cardiovascular and renal function.
